Communicable Diseases Intelligence

Communicable Diseases Intelligence (CDI) is a peer-reviewed scientific journal published by the Health Protection Policy & Surveillance Division, Department of Health and Aged Care.

The journal aims to disseminate information on the epidemiology, surveillance, prevention and control of communicable diseases of relevance to Australia.

COVID-19 Australia: Epidemiology Report 84

Reporting period ending 11 February 2024

Viral Respiratory Diseases Epidemiology and Surveillance Section

Summary

Four-week reporting period (15 January – 11 February 2024)

Case definitions for confirmed and probable cases are in accordance with the coronavirus disease 2019 (COVID-19) CDNA National Guidelines for Public Health Units.

Trends – Nationally, case notifications increased from early October 2023, and appeared to have gradually declined since the first week of January 2024. In the four-week period 15 January – 11 February 2024, there were 24,633 confirmed and 7,198 probable cases of COVID-19, a total of 31,831 COVID-19 cases reported in Australia to the National Notifiable Diseases Surveillance System (NNDSS). In the most recent reporting fortnight, a total of 14,913 confirmed and probable cases were notified (an average of 1,065 cases per day), compared to 16,918 in the previous fortnight (an average of 1,208 cases per day), representing a 11.9% fortnight-on-fortnight decrease.

Age group – Since the start of the sixth Omicron wave in mid-August 2023, the notification rates among most age groups have stabilised, except among adults aged 70 years and over where rates have slowly increased and subsequently reached an apparent peak in mid-November 2023. In the overall Omicron wave to date, the highest notification rate was observed among adults aged 20–29 years, whilst the lowest rate was among older adults aged 70–79 years.

Aboriginal and Torres Strait Islander people – In the reporting period 15 January – 11 February 2024, there were 991 new cases notified in Aboriginal and Torres Strait Islander people, accounting for 3.1% of all notified cases (991/31,831) during this time. In the Omicron wave to date (15 December 2021 – 11 February 2024), notifications among Aboriginal and Torres Strait Islander people have comprised 3.7% of all cases (437,196/11,802,869).

Severity – Since the emergence of the Omicron variant, there has been a consistent decrease in the incidence of severe illness, with a smaller severe-illness peak observed with each subsequent Omicron wave. Decreasing incidence may be due to high COVID-19 vaccination coverage, hybrid immunity and access to oral antiviral treatments. Since the start of the sixth Omicron wave, the weekly number of cases with severe illness reached an apparent peak in mid-November 2023. The crude case fatality rate from the start of the Omicron wave to date was 0.19%, which was lower than the crude rate during the Delta wave (0.71%).

Virology – For samples collected in the four-week period 15 January – 11 February 2024, all sequences uploaded to AusTrakka were assigned as Omicron strains or as recombinants consisting of Omicron lineages. There were 409 sequences uploaded to AusTrakka during 15 January – 11 February 2024. In this reporting period, most of the sequences analysed (85.6%) were BA.2 sub-sub lineages; 14.4% were recombinant or recombinant sub-lineages.

Acute respiratory illness – Based on self-reported FluTracking data, over the current four-week period, the weekly average proportions of ‘fever and cough’ (1.1%) and ‘runny nose and sore throat’ symptoms (0.8%) were respectively above and similar to proportions observed during the same period in 2023.

International situation – According to the World Health Organization (WHO), as of 4 February 2024, over 774 million COVID-19 cases and over 7 million deaths have been reported globally since the start of the pandemic, with a global case fatality rate (CFR) of approximately 0.91%.

Keywords: SARS-CoV-2; novel coronavirus; coronavirus disease 2019; COVID-19; acute respiratory disease; epidemiology; Australia

This reporting period covers the four-week period 15 January – 11 February 2024. Within this period, data for each fortnight is compared. The previous reporting period was the preceding four weeks (18 December 2023 – 14 January 2024).¹ The focus of this report is on the epidemiological situation in Australia since the beginning of the Omicron wave. For the purposes of this report, 15 December 2021 is used as a proxy for the beginning of the Omicron wave. This date was chosen as, from this date onward, most sequenced strains from cases were Omicron. Readers are encouraged to consult prior reports in this series for information on the epidemiology of coronavirus disease 2019 (COVID-19) in Australia.

Methods of data analysis in these reports have changed over the course of this reporting series to date. Please refer to the Technical Supplement for details of such changes, and for definitions of terminology.²

From Report #72 onward, and unless specified otherwise, all data from the National Notifiable Diseases Surveillance System (NNDSS) have been extracted using ‘diagnosis date’ rather than ‘notification received date’ (see the Technical Supplement for definitions). Due to COVID-19 reporting changes in several states and territories, the use of ‘diagnosis date’ now provides a more consistent and accurate method for describing transmission trends in Australia.

The case data provided includes both confirmed cases and probable cases reported to the NNDSS, as defined in accordance with the COVID-19 Communicable Diseases Network Australia (CDNA) National Guidelines for Public Health Units.³ For the purposes of this report, only probable cases from 5 January 2022 were included. Six jurisdictions have ceased collecting and reporting data on probable COVID-19 cases: Victoria ceased collection on 1 July 2023; Queensland on 1 September 2023;

New South Wales on 1 October 2023; Western Australia on 9 October 2023; the Northern Territory on 21 October 2023; and the Australian Capital Territory on 22 December 2023. Rapid antigen tests (RATs) administered in healthcare or aged care settings continue to be reported to the NNDSS by some jurisdictions.

From Report #71 onward, population data for Aboriginal and Torres Strait Islander people was updated (from 2016) and is now based on the Australian Bureau of Statistics (ABS) Estimated Resident Population (ERP) as at 2021. There has been an increase of 185,600 Aboriginal and Torres Strait Islander people (23.2%) since the previous ERP (June 2016). Therefore, notification rate comparisons with reports prior to #71 should be undertaken with caution.

Due to the dynamic nature of data in the NNDSS, numbers may be subject to revision and may vary from numbers previously reported and from case notifications released by states and territories.

Background and data sources

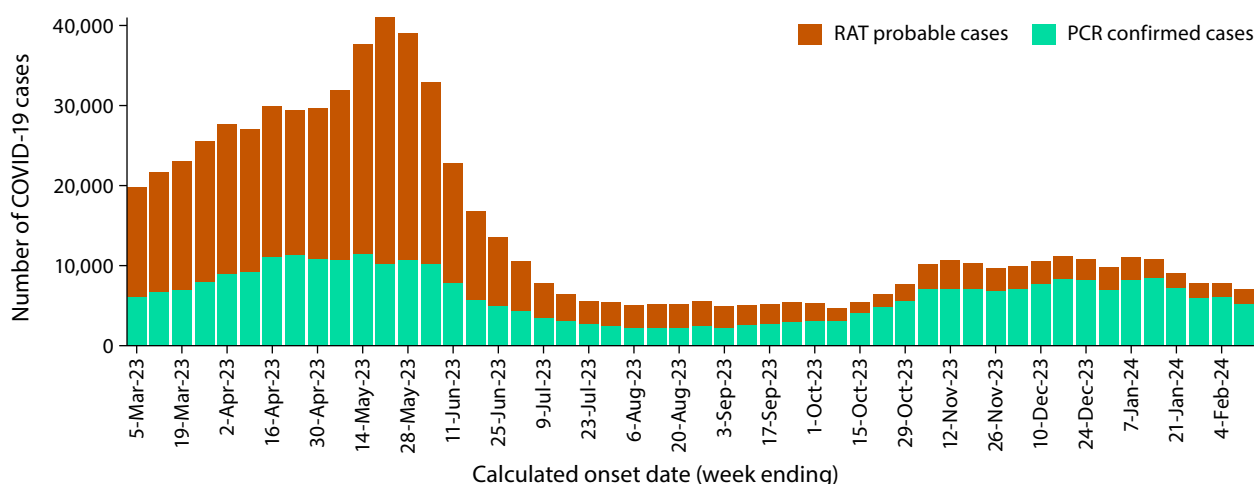

See the Technical Supplement for general information on COVID-19 including modes of transmission, common symptoms, and severity.²

Activity

COVID-19 trends (NNDSS)

Since the beginning of the pandemic to 11 February 2024, jurisdictions in Australia have reported 11,802,869 COVID-19 cases to the NNDSS. Nationally, case notifications have followed a decreasing trend since early January 2023 (Figure 1).

Figure 1: Confirmed and probable COVID-19 cases notified to the NNDSS by date of onset, Australia, 27 February 2023 – 11 February 2024^{a,b}

a Source: NNDSS, extracted on 14 February 2024 for cases with an illness onset from 27 February 2023 to 11 February 2024.

b Since 1 July 2023, several jurisdictions have progressively ceased collecting and reporting data on probable COVID-19 cases.

b ACT: Australian Capital Territory; NSW: New South Wales; NT: Northern Territory; Qld: Queensland; SA: South Australia; Tas.: Tasmania; Vic.: Victoria; WA: Western Australia.

c Since 1 July 2023, cases are classified based on jurisdiction of residence. This does not necessarily reflect the place where the disease was acquired or where the case presented. Please note prior to this, cases were classified based on the jurisdiction in which they tested positive.

d Six jurisdictions have ceased collecting and reporting data on probable COVID-19 cases: Victoria ceased collection on 1 July 2023; Queensland on 1 September 2023; New South Wales on 1 October 2023; Western Australia on 9 October 2023; the Northern Territory on 21 October 2023; and the Australian Capital Territory on 22 December 2023. Rapid antigen tests (probable COVID-19 cases) administered in healthcare or aged care settings continue to be reported to the NNDSS by some of these jurisdictions.

In the four-week period 15 January – 11 February 2024, there were 24,633 confirmed and 7,198 probable cases of COVID-19 reported in Australia to the NNDSS (Table 1). In the most recent reporting fortnight, a total of 14,913 confirmed and probable cases were notified (an average of 1,065 cases per day), compared to 16,918 in the previous fortnight (an average of 1,208 cases per day), representing a 11.9% fortnight-on-foortnight decrease.

As the pandemic has progressed, the proportion of cases reported through traditional surveillance has decreased and there are many different sub-lineages of virus circulating simultaneously. Additionally, increases in other measures of disease activity, such as the numbers of people admitted to hospital, to intensive care units (ICU), or having died, often lag weeks behind increases in infections in the community. This has made defining the start of a new wave more complex, with the determination often now only possible several weeks after the wave has commenced.

Since the emergence of the Omicron variant in Australia, there have been six distinct waves of transmission, defined either by the predominant Omicron subvariant circulating, or a combination of existing and newly emerging Omicron subvariants. The first wave of the BA.1 subvariant occurred from mid-December 2021 to February 2022, with a peak in cases observed in early January 2022. From March 2022, the BA.2 subvariant was the predominant strain; in this second Omicron wave, there was a primary peak in early April and a secondary peak in late May 2022. In early July 2022, BA.5 (including sub-lineages) became the predominant subvariant detected in Australia, driving a third wave

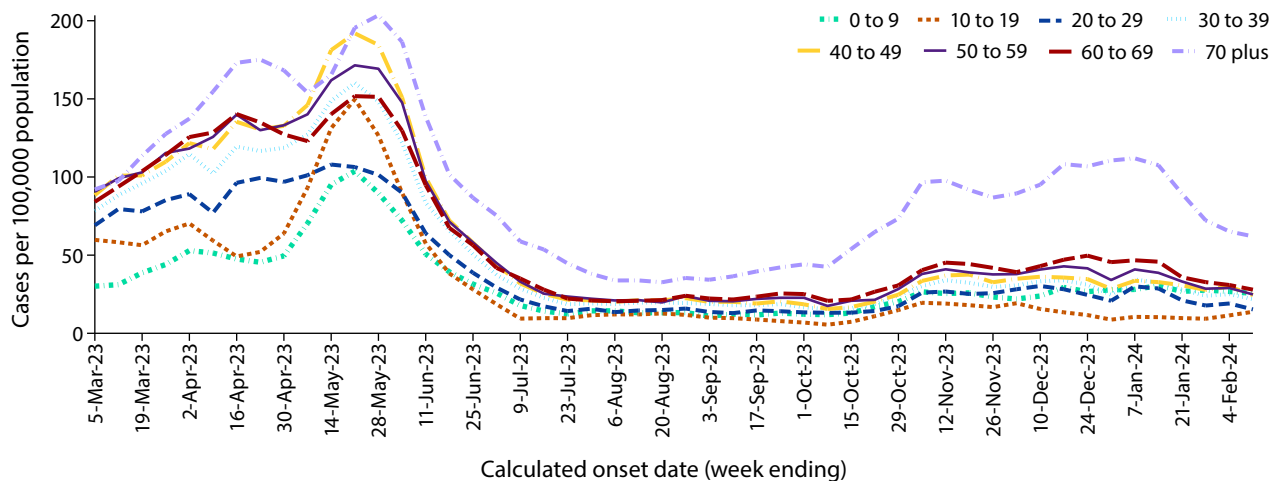

of transmission which peaked in the week ending 24 July 2022. A fourth wave of transmission commenced in late October 2022, driven by a combination of existing and newly emerging Omicron subvariants. This wave peaked during the week ending 11 December 2022. A fifth Omicron wave of transmission, similarly driven by a combination of existing and newly emerging recombinant Omicron subvariants, commenced in early March 2023 and led to a peak in case notifications in the week ending 21 May 2023 (Figure 1). The most recent sixth wave of transmission, also driven by a combination of existing and newly emerging recombinant Omicron subvariants (XBB*), commenced in late August 2023, signalled by an increasing trend in several surveillance indicators (Figures 1, 3 and 5). Holiday-related population mixing, particularly across the four-week period 15 January 2024 – 11 February 2024, the newly emerging Omicron BA.2.86.1.1 (JN.1) sub-lineage and waning of hybrid immunity may explain the prolonged sixth Omicron wave.

Due to a reduction in case ascertainment in all jurisdictions, including changes in testing and reporting requirements, reported case numbers underestimate disease incidence in the community.

Demographic features (NNDSS)

Following the start of the sixth Omicron wave in mid-August 2023, notification rates among most age groups have remained relatively low and stable, except among adults aged 70 years and over where rates slowly increased and remain the highest notification rates among all age groups (Figure 2).

Figure 2: Confirmed and probable COVID-19 crude notification rates for ten-year age groups by date of onset, Australia, 27 February 2023 – 11 February 2024^{a,b}

a Source: NNDSS, extracted on 14 February 2024 for cases with an illness onset from 27 February 2023 to 11 February 2024.

b Population data based on Australian Bureau of Statistics (ABS) Estimated Resident Population (ERP) as at June 2023.

This is likely a reflection of higher case ascertainment due to targeted testing in this age group that is at higher risk of severe disease. In the current reporting period, 15 January – 11 February 2024, the highest notification rate was observed among adults aged 70 years and over (Figure 2). In the Omicron wave to date the highest notification rate was observed among adults aged 20–29 years, whilst the lowest rate was among older adults aged 70–79 years (Appendix A, Table A.1).

Aboriginal and Torres Strait Islander persons (NNDSS)

Overall, since the start of the pandemic, Aboriginal and Torres Strait Islander status is unknown for approximately 13.4% of COVID-19 notifications in NNDSS. Therefore, the number of cases classified as Aboriginal and Torres Strait Islander people is likely an under-representation. During the reporting period, there were 991 new cases notified among Aboriginal and Torres Strait Islander people (Table 2). In the Omicron wave to date (15 December 2021 – 11 February 2024), notifications among Aboriginal and Torres Strait Islander people comprised 3.7% (437,196/11,802,869) of all cases.

Of the COVID-19 cases notified among Aboriginal and Torres Strait Islander people from 15 December 2021 to date, and where location of residence was known, 55.0% (233,204/424,052) lived in a regional or remote area (Table 3).

Nationally, there have been 448 COVID-19 related deaths among Aboriginal and Torres Strait Islander people notified to the NNDSS from the start of the pandemic to 11 February 2024. This comprises 144 (32.1%) from New South Wales; 135 (30.1%) from Queensland; 63 (14.1%) from Western Australia; 58 (13.0%) from the Northern Territory; 25 (5.6%) from South Australia; 19 (4.2%) from Victoria; and two (0.5%) each from the Australian Capital Territory and Tasmania. Nationally, there have been 791 COVID-19 associated intensive care admissions among Aboriginal and Torres Strait Islander people notified to the NNDSS from the start of the pandemic to 11 February 2024. In the Omicron wave to date, the rate of severe illness increased with higher age, with the highest rate observed among those aged 70 years and over (Table 4). It should be noted that ICU status in NNDSS is likely incomplete.

Table 2: Confirmed and probable COVID-19 cases among Aboriginal and Torres Strait Islander people notified to the NNDSS by jurisdiction and date of onset, Australia, 1 January 2020 – 11 February 2024^{a,b,c}

- a Rate per 100,000 population for the given time period. Aboriginal and Torres Strait Islander population data is based on the Australian Bureau of Statistics (ABS) Estimated Resident Population (ERP) as at 2021.

Severity (NNDSS, FluCAN, SPRINT-SARI)

To provide a more accurate assessment of severity (defined as those admitted to ICU and/or died), cases with an illness onset in the last two weeks of the reporting period have been excluded from the analyses, given the delay between illness onset and development of severe illness.

Since the emergence of the Omicron variant, the number of cases with severe illness peaked in mid-January 2022, at over 1,260 severe cases per week (data not shown). Since this time there has been a consistent decrease in the incidence of severe illness, with a smaller peak observed with each subsequent Omicron wave. This is likely due to a combination of factors such as high COVID-19 vaccination coverage, hybrid immunity and access to oral antiviral treatments. Since the start of the sixth Omicron wave, the incidence of severe illness gradually increased and reached an apparent peak at approximately 200 severe cases in the week ending 12 November 2023 (Figure 3). Since mid-November 2023, there has been an overall decreasing trend in the number of cases developing severe illness; however, week-on-week increases have been observed.

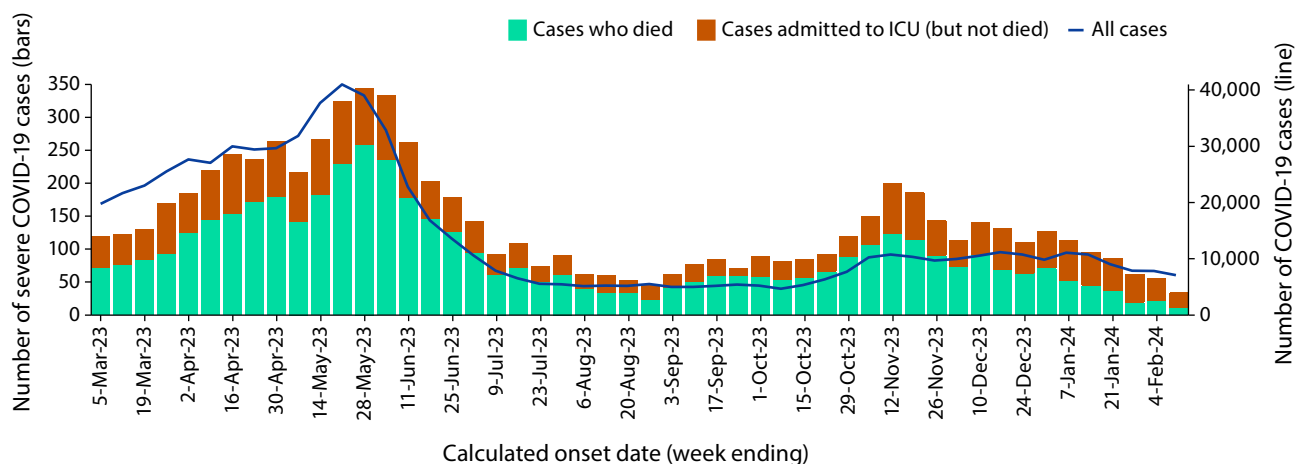

Similar to previous transmission waves, rates of severe illness during the Omicron waves remain highest in older age groups, particularly those aged 70 years and older (Figure 4). The rate of severe illness in this age group has increased gradually since

the start of the sixth Omicron wave and subsequently reached an apparent peak in mid-November 2023 at just above 4 cases per 100,000 population per week. In comparison, rates of severe illness in younger age groups have remained relatively low and stable throughout the current sixth Omicron wave and earlier Omicron waves, not surpassing 1.3 cases per 100,000 population per week since the start of the fifth Omicron wave (Figure 4).

Hospitalisation and ICU admissions Influenza Complications Alert Network—FluCAN

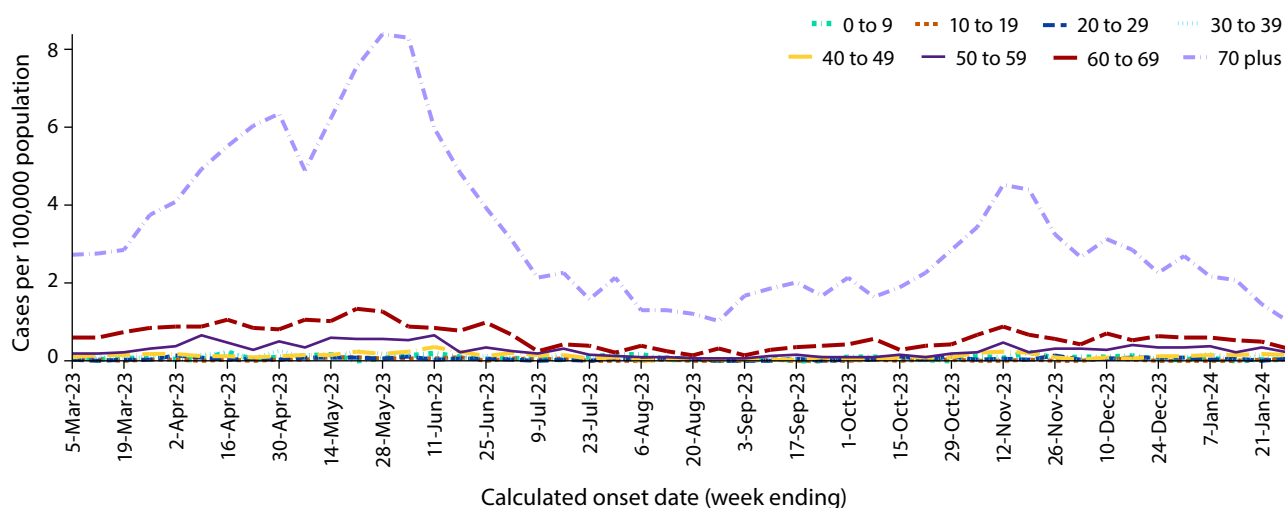

Between 15 December 2021 and 11 February 2024, there were 20,147 hospital admissions with confirmed COVID-19 reported at Influenza Complications Alert Network (FluCAN) sentinel sites, including 5.7% (1,145/20,147) admitted directly to ICU. Since the start of the fifth Omicron wave, there were 5,530 hospital admissions with confirmed COVID-19 reported at FluCAN sentinel sites, including 6.0% (331/5,530) admitted directly to ICU (Figure 5). During the latest four-week reporting period (15 January – 11 February 2024), there were 254 hospital admissions with COVID-19 reported at FluCAN sentinel sites, with 7.5% (19/254) admitted directly to ICU. The proportion of COVID-19 ICU admissions in the year to date (1 January to 11 February 2024) was 6.0% (28/470), slightly higher than the proportion for the same period in 2023 (5.3%; 45/853).

Figure 3: Confirmed and probable COVID-19 cases, intensive care admissions and deaths notified to the NNDSS by date of onset, Australia, 27 February 2023 – 11 February 2024^{a,b}

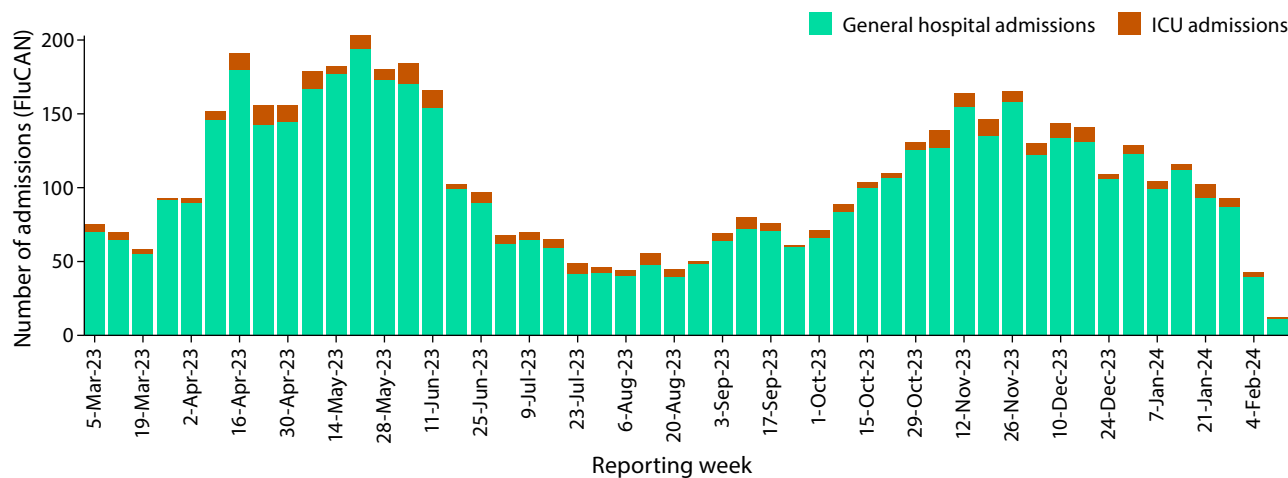

- a Source: NNDSS, extracted on 14 February 2024 for cases with an illness onset from 27 February 2023 to 11 February 2024.
b Shaded bars at the right represent the most recent two reporting weeks and should be interpreted with caution, as cases with an illness onset in these weeks may not have yet developed severe disease.

Figure 4: Notification rates of COVID-19 cases admitted to intensive care or died for ten-year age groups by date of onset, Australia, 27 February 2023 to 28 January 2024^{a,b}

- a Source: NNDSS, extracted on 14 February 2024 for cases with an illness onset from 27 February 2023 to 28 January 2024; cases with an illness onset in the last two weeks (29 January – 11 February 2024) were excluded to account for the delay between onset and development of severe illness.
- b Population data based on Australian Bureau of Statistics (ABS) Estimated Resident Population (ERP) as at June 2023.

Short Period Incidence Study of Severe Acute Respiratory Infection—SPRINT-SARI

Between 15 December 2021 and 11 February 2024, there were 6,974 COVID-19 cases admitted to ICUs participating in the sentinel surveillance system, Short Period Incidence Study of Severe Acute Respiratory Infection (SPRINT-SARI)⁵ (Table 5). Most patients (62.6%; 4,363/6,974) were discharged home. Thirteen percent (887/6,974) died in ICU and 5.2% (365/6,974) died within the general hospital ward, with an overall in-hospital mortality rate of 18.0% (1,252/6,974).

Since the start of the Omicron wave (15 December 2021) to 11 February 2024, for patients admitted to SPRINT-SARI sentinel sites with COVID-19 ($n = 6,974$), the median duration of mechanical ventilation was 4.0 days (interquartile range [IQR]: 1.6–9.0 days); the median length of stay in ICU was 3.4 days (IQR: 1.7–7.2 days); and the median length of stay in hospital was 11.0 days (IQR: 6.0–20.0 days).

In the four-week reporting period (15 January – 11 February 2024), there were 52 adult patients with COVID-19 (34 males, 18 females; median age: 70 years; IQR: 58.3–78.3 years) admitted to ICU

Table 5: Patient outcomes for adult COVID-19 cases (aged greater than or equal to 18 years), Australia, 15 December 2021 – 11 February 2024^a

Outcomes	Reporting period	Omicron wave to date
	15 January – 11 February 2024 (n = 52)	15 December 2021 – 11 February 2024 (n = 6,974)
Patient status		
Ongoing care in ICU	13 (25.0%)	30 (0.4%)
Ongoing care in hospital ward ^b	15 (28.8%)	33 (0.5%)
Transfer to other hospital/facility	0 (0%)	516 (7.4%)
Transfer to rehabilitation	0 (0%)	678 (9.7%)
Discharged home	15 (28.8%)	4,363 (62.6%)
Mortality – ICU	6 (11.5%)	887 (12.7%)
Mortality – hospital ward	2 (3.8%)	365 (5.2%)
Unknown	0 (0%)	71 (1.0%)
Missing ^c	1 (1.9%)	31 (0.4%)

a Source: SPRINT-SARI.⁵

b Patients who were admitted in ICU/hospital wards with no discharge information for less than 90 days were assumed to have ongoing care in the hospital.

c Patients who were admitted to ICU/hospital wards for more than 90 days with no discharge information were treated as ‘missing data’.

reported at contributing SPRINT-SARI sentinel sites (Table 5). During the four-week reporting period (15 January – 11 February 2024), for adult patients admitted to contributing SPRINT-SARI sentinel sites with COVID-19 (n = 52), the median duration of mechanical ventilation was 0.83 days (IQR: 0.55–3.9 days); the median length of stay in ICU was 2.3 days (IQR: 1.4–4.0 days); and the median length of stay in hospital was 6.2 days (IQR: 4.6–9.7 days).

Risk factors for severe disease

Comorbidity data extracted from SPRINT-SARI reflect the sickest patients with COVID-19 who are managed in ICU; data are therefore not generalisable to all cases. Figure 6 shows the most prevalent comorbidities among adult patients admitted to SPRINT-SARI sentinel ICUs with COVID-19 during the four-week period 15 January – 11 February 2024, where comorbidity information was available. Of those adult patients admitted to sentinel ICUs during the four-week reporting period, for whom comorbidity data was known, 46.2% (24/52) had three or more comorbidities (data not shown).

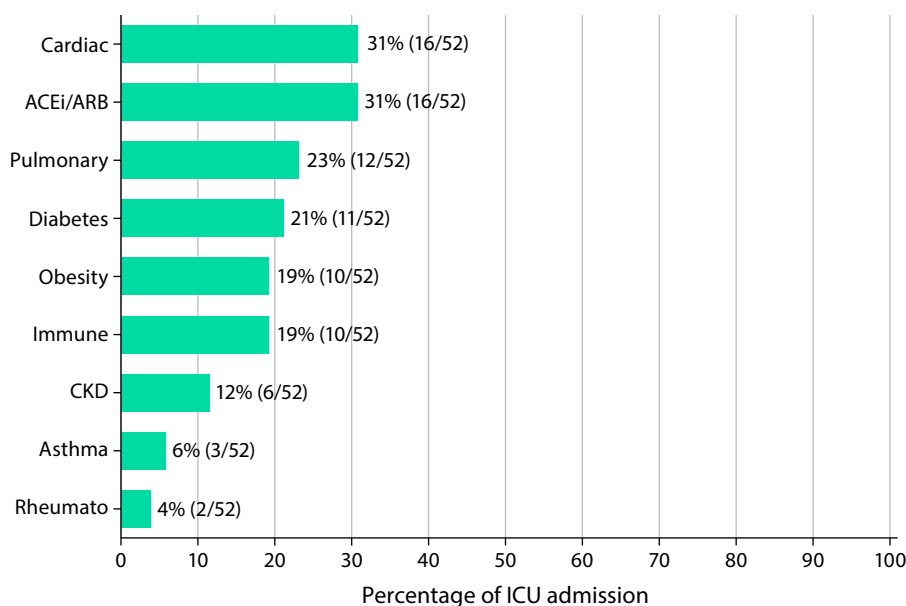

Paediatric Inflammatory Multisystem Syndrome – Temporally Associated with SARS-CoV-2 *Paediatric Active Enhanced Disease Surveillance*

Since the start of the pandemic to 11 February 2024, there have been 190 cases of paediatric inflammatory multisystem syndrome – temporally associated with SARS-CoV-2 (PIMS-TS) reported to the Paediatric Active Enhanced Disease Surveillance network (PAEDS), including 24 PIMS-TS cases reported in 2023. There were no cases during the current reporting period, but three new cases were reported from a previous reporting period (Figure 7). The majority of PIMS-TS cases to date have occurred in those aged 5 to < 12 years (53%; 100/190), followed by those aged 6 months to < 5 years (28%; 53/190). To date, there have been no PIMS-TS associated deaths.

COVID-19 deaths

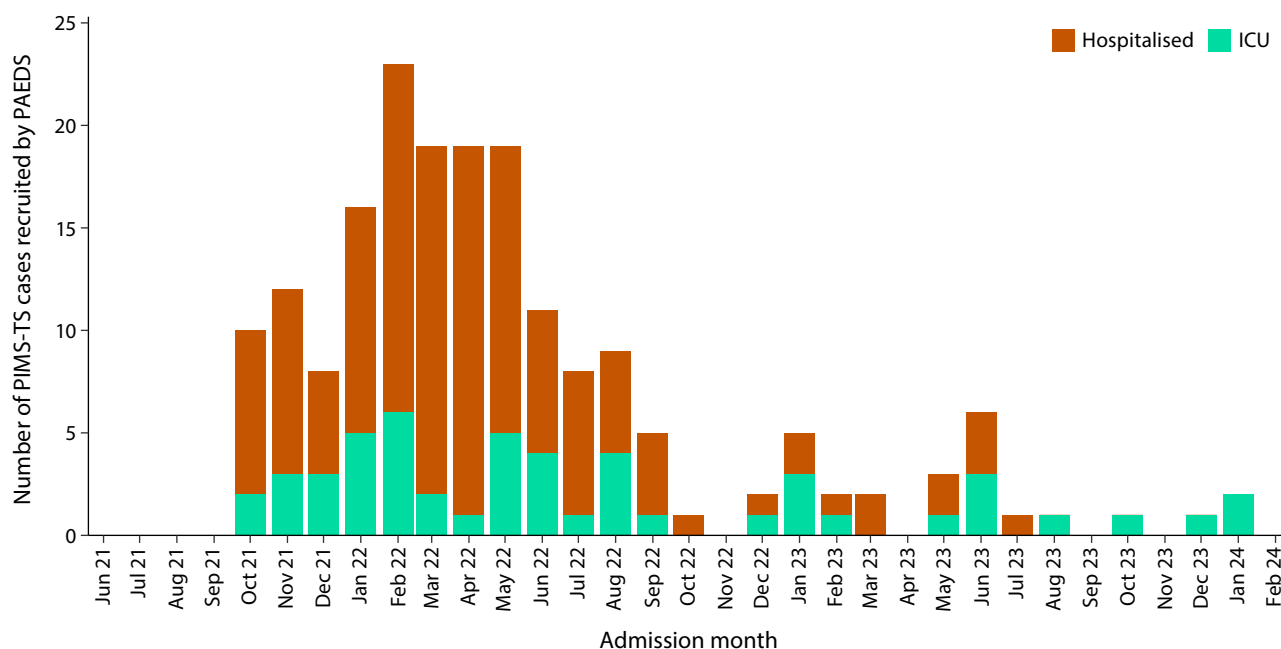

Since the beginning of the pandemic to 11 February 2024, there have been 24,684 COVID-19 related deaths reported to the NNDSS, with 1,689 COVID-19 related deaths notified in the sixth Omicron wave to date (Table 6). The crude case fatality rate from the start of the overall Omicron wave to date is 0.19%, which is lower than the crude case fatality rate for the Delta wave (0.71%) (Table 7).

Figure 6: Prevalence of comorbidities for COVID-19 cases among admitted adult ICU patients (aged greater than or equal to 18 years), Australia, 15 January 2024 – 11 February 2024^{a,b}

- a Source: SPRINT-SARI. Only includes adult cases (≥ 18 years old) and excludes those with missing data on comorbidities or where comorbidity is unknown.
- b Abbreviated comorbidities defined as: Cardiac: chronic cardiac disease; ACEi/ARB: past use of ACE inhibitor or A2 Blocker; CKD: chronic kidney disease; Immune: chronic immunosuppression; Pulmonary: chronic pulmonary disease (not including asthma); and Rheumato: rheumatologic disorder.

a Source: NNDSS, extracted on 14 February 2024 for deaths with an illness onset date to 11 February 2024.

b Deaths are categorised into time periods using date of death. Deaths with a missing date of death are classified using date of illness onset.

c ACT: Australian Capital Territory; NSW: New South Wales; NT: Northern Territory; Qld: Queensland; SA: South Australia; Tas.: Tasmania; Vic.: Victoria; WA: Western Australia.

d Six jurisdictions have ceased collecting and reporting data on probable COVID-19 cases: Victoria ceased collection on 1 July 2023; Queensland on 1 September 2023; New South Wales on 1 October 2023; Western Australia on 9 October 2023; the Northern Territory on 21 October 2023; and the Australian Capital Territory on 22 December 2023. Rapid antigen tests (probable COVID-19 cases) administered in healthcare or aged care settings continue to be reported to the NNDSS by some of these jurisdictions.

Table 7: COVID-19 associated case fatality rates among cases notified to NNDSS, by age group and date of onset, 1 January 2020 to 28 January 2024^{a,b,c}

Age group (years)	Omicron wave to date 15 December 2021 – 28 January 2024	Delta wave 16 June – 14 December 2021	Pandemic to date 1 January 2020 – 28 January 2024
0–9	< 0.05%	< 0.05%	< 0.05%
10–19	< 0.05%	< 0.05%	< 0.05%
20–29	< 0.05%	< 0.05%	< 0.05%
30–39	< 0.05%	0.06%	< 0.05%
40–49	< 0.05%	0.18%	< 0.05%
50–59	< 0.05%	0.65%	0.06%
60–69	0.18%	1.97%	0.21%
70+	2.06%	10.91%	2.24%
Australia	0.19%	0.71%	0.21%

a Source: NNDSS, extracted on 14 February 2024 for deaths with an illness onset date to 28 January 2024.

b To account for the lag between illness onset and the development of severe illness, cases with an onset date in the last two weeks have been excluded from calculations of the case fatality rate.

c Crude case fatality rates which reflect number of deaths as a proportion of reported COVID-19 cases during specific periods. Note, the current crude case fatality rates are likely overestimated due to changes in case ascertainment and increased underreporting of non-severe cases.

Genomic surveillance and virology (Communicable Disease Genomics Network, AusTrakka and jurisdictional sequencing laboratories)

Variants of concern (VOC)

AusTrakka⁶ is actively monitoring and reporting on one lineage and its associated sub- and sub-sub-lineages, currently designated as a variant of concern (VOC) by international organisations, including the World Health Organization (WHO): Omicron (B.1.1.529). The Omicron variant displays a characteristic set of mutations which differentiate the lineage from previously circulating VOCs. Further information on variants and their mutations is available in the Technical Supplement.²

There have been five major sub-lineages defined under B.1.1.529: BA.1, BA.2, BA.3, BA.4 and BA.5, and a large number of sub-lineages, including recombinants, under these; all are designated Omicron. Unlike previous periods in Australia's COVID-19 waves, where one or two dominant lineages were the main driver of disease, there is currently significant diversity in the range of sub-sub-lineages circulating within Australia. During this period, more than 200 unique lineages have been identified, and it is likely that there are more that are not being characterised through whole genome sequencing. This diversity of circulating lineages has sometimes been referred to as a 'variant soup'. Many of these circulating lineages will die out without causing a significant disease burden, but others appear to have stronger growth potential.

Variants of interest and variants under monitoring

The Communicable Diseases Genomics Network (CDGN) VOC working group tracks notable SARS-CoV-2 variants, including:

- variants of interest (VOI): XBB.1.5, XBB.1.16, EG.5, BA.2.86*, JN.1; and
- the following variants under monitoring (VUM) and their descendent lineages: BA.2.75 and BA.2.75.2 (including CH*), and recombinants XBB* (in particular XBB.1.9.1* and XBB.1.9.2*), and XBF*.

This report uses the VOI classification for lineages with possible evidence for epidemiological, pathological or immunological features of concern. This is consistent with CDGN usage and with the WHO use of the term.^{7,8} VUMs are other lineages with early observations of potential significance, but little to no evidence of current concern. In this report, details are included of Omicron subvariants under monitoring as designated by the WHO.

AusTrakka SARS-CoV-2 genomic epidemiology

From 15 January to 11 February 2024, there were 409 sequences uploaded to AusTrakka. This represents a 41% decrease in the number of sequences compared to the previous reporting period. All sequences uploaded during this reporting period have been assigned to sub-lineages within B.1.1.529 (Omicron) or to recombinants consisting of one or more Omicron sub-lineages.

Of the 409 sequences uploaded to AusTrakka between 15 January and 11 February 2024:

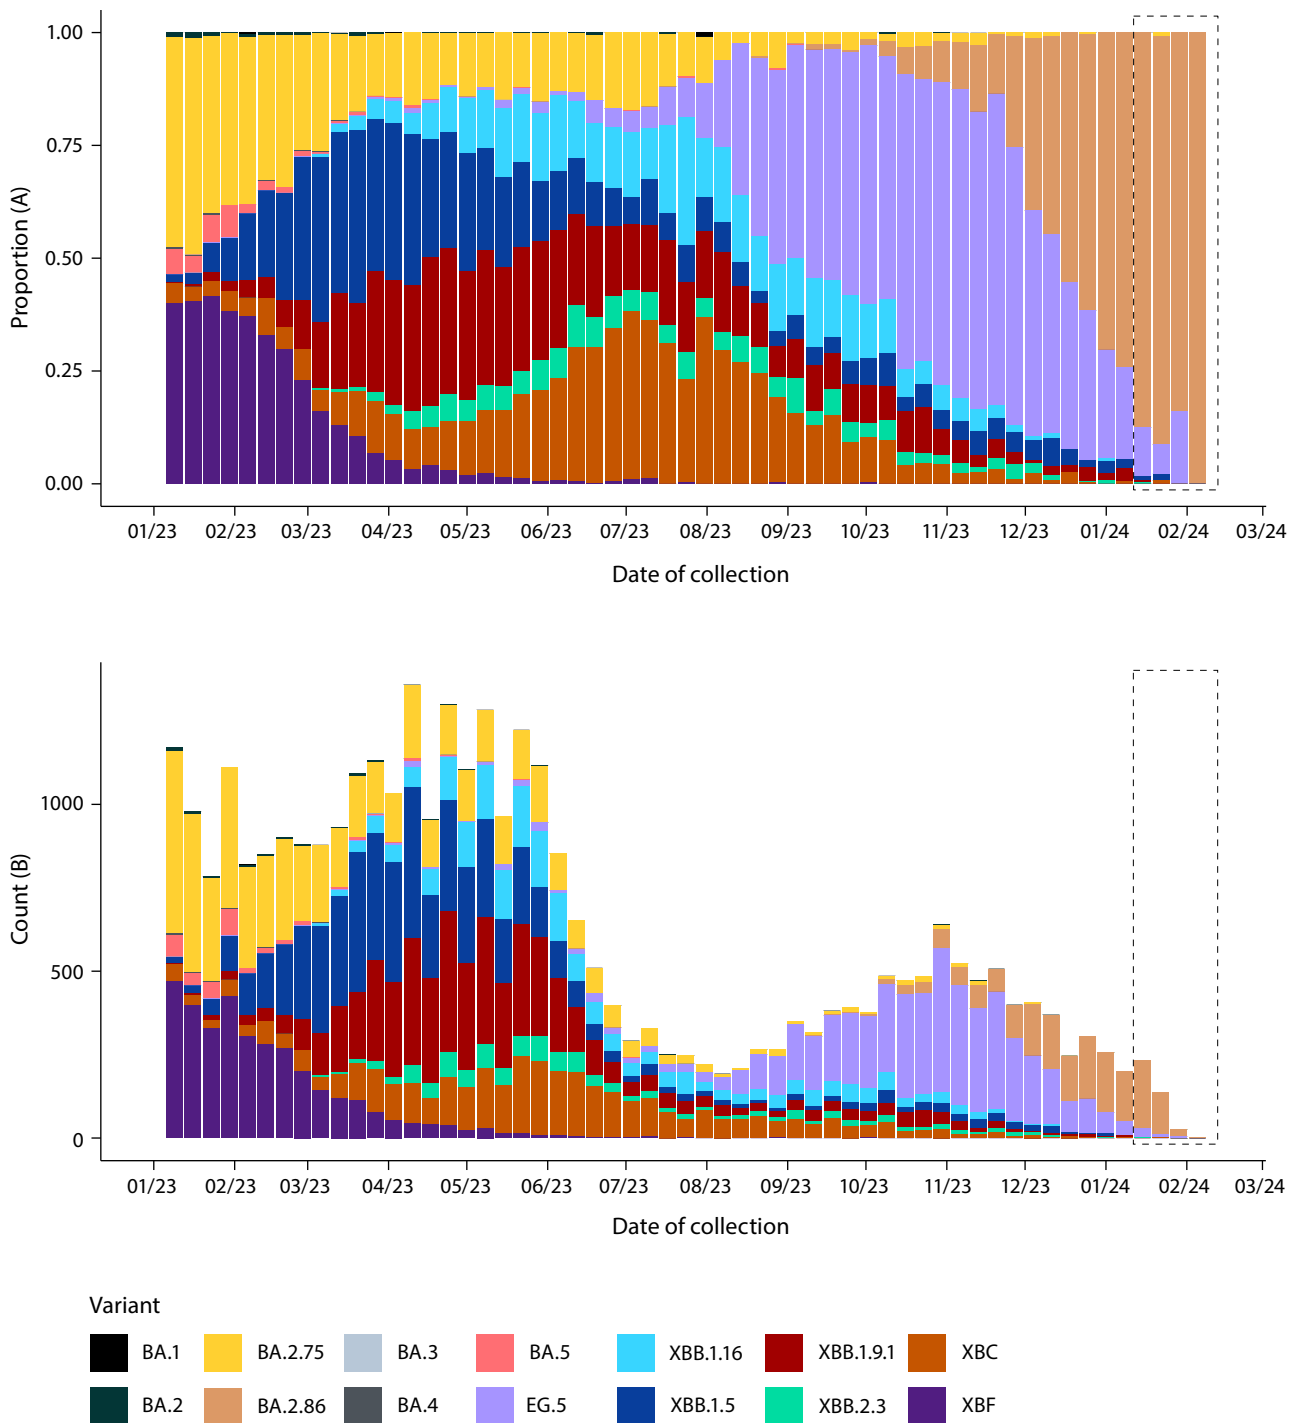

- 14.4% (59/409) were recombinant or recombinant sub-lineages; and
- 85.6% (350/409) were BA.2 sub-sub-lineages.

No BA.1, BA.3, BA.4 or BA.5 Omicron sub-lineages were identified.

From 1 July 2023, jurisdictional sequencing strategies for SARS-CoV-2 have changed. Some jurisdictions have ceased SARS-CoV-2 sequencing, while other jurisdictions have reduced the number of SARS-CoV-2 cases being sequenced. For jurisdictions which are continuing SARS-CoV-2 genomic surveillance, SARS-CoV-2 cases which are likely to be prioritised for sequencing include ICU or hospitalised cases, high-risk cases, or cases of clinical significance. As a result, these changes are likely to affect the representativeness of the distribution of sequenced SARS-CoV-2 sub-lineages across Australia.

Case numbers and sequencing proportion are primarily based on polymerase chain reaction (PCR) results only, as RATs do not allow for sequencing. Since late 2022, the rates of PCR for testing and subsequent referrals of positive PCR samples to sequencing laboratories have decreased significantly, resulting in changes to sequencing strategies across the country.

Figure 8: Omicron sub-lineage in Australia since 1 January 2023 by sample collection date, showing (A) proportions and (B) count per week^{a,b,c}

- a Sequences in AusTrakka aggregated by epidemiological week.
- b The dashed box indicates the distribution of sequences collected within the reporting period.
- c Proportions in Figure 8A may not be representative when sequence numbers are small; refer to Figure 8B. Data for earlier epidemiological weeks may change between reporting periods as sequences with older collection dates are uploaded. These numbers are not equivalent to number of cases, as there are many cases which may not be sequenced. Non-VOI and non-VUM Omicron sub-lineages have been collapsed into parent lineages BA.1, BA.2, BA.3, BA.4 and BA.5.

Table 8: Australian SARS-CoV-2 genome sequences in AusTrakka, identified as variants of concern, variants of interest or variants under monitoring and proportion of positive cases sequenced for the current and previous reporting periods, and since 23 January 2020^{a,b,c}

Variant category	Measure	Reporting period 15 January 2024 – 11 February 2024	Previous reporting period 18 December 2023 – 14 January 2024	Total sequences to date 23 January 2020 – 11 February 2024
Variants of concern (VOC)	BA.1	0 (0%)	0 (0%)	26,272 (15.7%)
	BA.2 (excluding BA.2.75)	349 (85.3%)	428 (61.8%)	42,052 (25.2%)
	BA.2.75	1 (0.24%)	1 (0.14%)	14,504 (8.7%)
	BA.3	0 (0%)	0 (0%)	3 (<0.1%)
	BA.4	0 (0%)	0 (0%)	5,052 (3.0%)
	BA.5	0 (0%)	0 (0%)	43,203 (25.9%)
	Total recombinants	59 (14.4%)	264 (38.1%)	36,060 (21.6%)
Total VOC		409 (100%)	693 (100%)	167,146 (100%)
Variants of interest (VOI)	XBB.1.5 + sub-lineages	4 (1.0%)	18 (2.6%)	5,825 (3.5%)
	XBB.1.16	0 (0%)	11 (1.6%)	4,574 (2.7%)
	EG.5 (XBB.1.9.2.5)	39 (9.5%)	187 (27.0%)	4,839 (2.9%)
	JN.1 (BA.2.86.1.1)	313 (76.5%)	353 (50.9%)	1,280 (0.77%)
	BA.2.86 + sub-lineages (incl. JN)	349 (85.3%)	428 (61.8%)	1,763 (1.1%)
Variants under monitoring (VUM)	XBB + all sub-lineages	50 (12.2%)	236 (34.0%)	24,473 (14.6%)
	XBB.1.9.1, XBB.1.9.2 + sub-lineages	44 (10.8%)	204 (29.4%)	10,258 (6.1%)
	XBB.2.3	2 (0.49%)	1 (0.14%)	1,418 (0.85%)
	XBF	0 (0%)	0 (0%)	6,437 (3.9%)
	XBC	4 (1.0%)	11 (1.6%)	4,563 (2.7%)
	DV.7 (CH.1.1.1)	1 (0.24%)	1 (0.14%)	123 (< 0.1%)
Omicron BA.2	BA.2.75 + sub-lineages	1 (0.24%)	1 (0.14%)	14,581 (8.7%)
	CH.1.1 + sub-lineages (BA.2.75.1.1)	1 (0.24%)	1 (0.14%)	4,469 (2.7%)

- a All lineages have been designated as variants of concern (VOC), variants of interest (VUI) or variants under monitoring (VUM) in Australia, by the CDGN VOC working group.
- b Based on individual jurisdictional reports of sequences and case numbers. Calculations of the percentage of cases sequenced based on the number of sequences available in AusTrakka may not always be up-to-date, since this may include duplicate samples from cases and may not represent all available sequence data. Total SARS-CoV-2 case numbers as reported by jurisdictional laboratories based on PCR results only. Cases identified via rapid antigen testing are reported differently by each jurisdiction and cannot be followed up for sequencing. They are therefore not included in the sequencing proportions reported here. Sequencing of samples from cases identified in the reporting period may be in process at the time of reporting. Remaining unsequenced samples may be due to jurisdictional sequencing strategy, or where samples have been deemed unsuitable for sequencing (typically because viral loads were too low for sequencing to be successful).
- c Proportional changes compared to the previous 28-day period are highlighted by the following colours: **green boxes indicate a decrease** and **orange boxes indicate an increase**.

The Australian SARS-CoV-2 genome sequences in AusTrakka identified as VOC, VOI or VUM are highlighted in Table 8. The VOI and VUM where the proportion has increased compared to the previous reporting period are highlighted in orange, those that have remained stable are highlighted in blue, while those where proportions have decreased are highlighted in green.

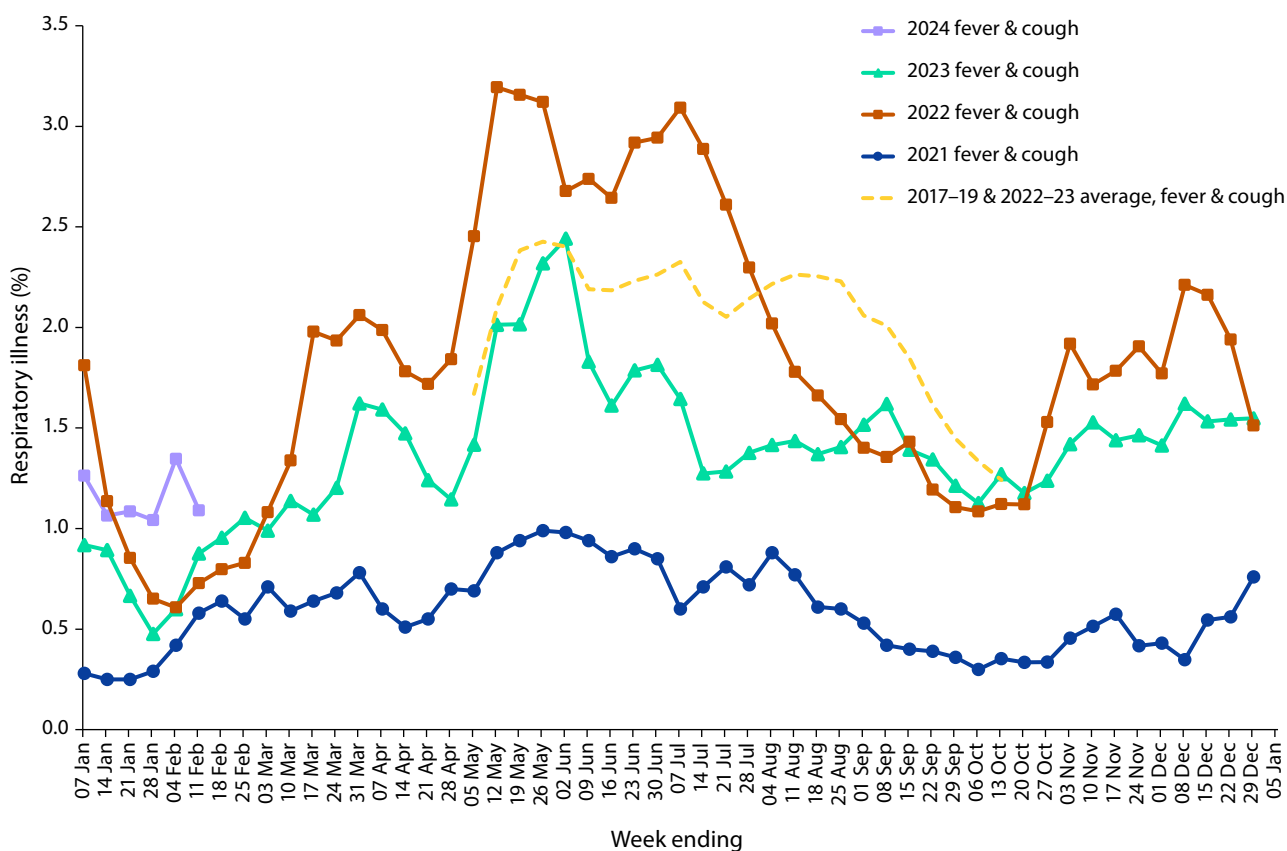

In the reporting period to 11 February 2024, the proportion of recombinant sublineages has again dropped, representing only 14.4% of all sequences this reporting period. This change in the dominant lineage is still being driven by BA.2, which made up the remaining 85.6% of all samples. More specifically, the increase in BA.2 is due to the continually increasing proportion of JN.1 (a sub-lineage of BA.2.86), which made up more than 76% of all sequences seen in this reporting period. This is up from the previous reporting period (Table 1) and is a rapid increase from the 16.3% noted in Report 82.⁹ In contrast all other lineages have continued to decline or have

persisted at very low levels. EG.5 (XBB.1.9.2.5), is down to 9.5% of samples uploaded in this report, while the remaining VOIs (XBB.1.16 and XBB.1.5) now appear uncommon, with no XBB.1.16 and only four XBB.1.5 uploaded in this four-week reporting period (Table 1). This change to a dominance of JN.1 is in line with international reports and sequencing databases.¹⁰

Acute respiratory illness (FluTracking, ASPREN)

Based on self-reported FluTracking data,¹¹ the incidence of ‘fever and cough’ symptoms increased from approximately 1.2% in mid-October 2023 to approximately 1.5% in early December 2023, but has decreased in recent weeks. The average proportion in the current four-week reporting period (15 January – 11 February 2024) remains higher than the proportion observed during the same period in 2023, at 1.1% (Figure 9).

Figure 9: Weekly trends in fever and cough amongst FluTracking survey participants (age-standardised) compared to the average of 2017–2019 & 2022–2023, Australia, 1 January 2021 – 11 February 2024^a

^a In years prior to 2020, FluTracking was activated during the main influenza season from May to October. A historical average beyond the week ending 13 October is therefore not available.

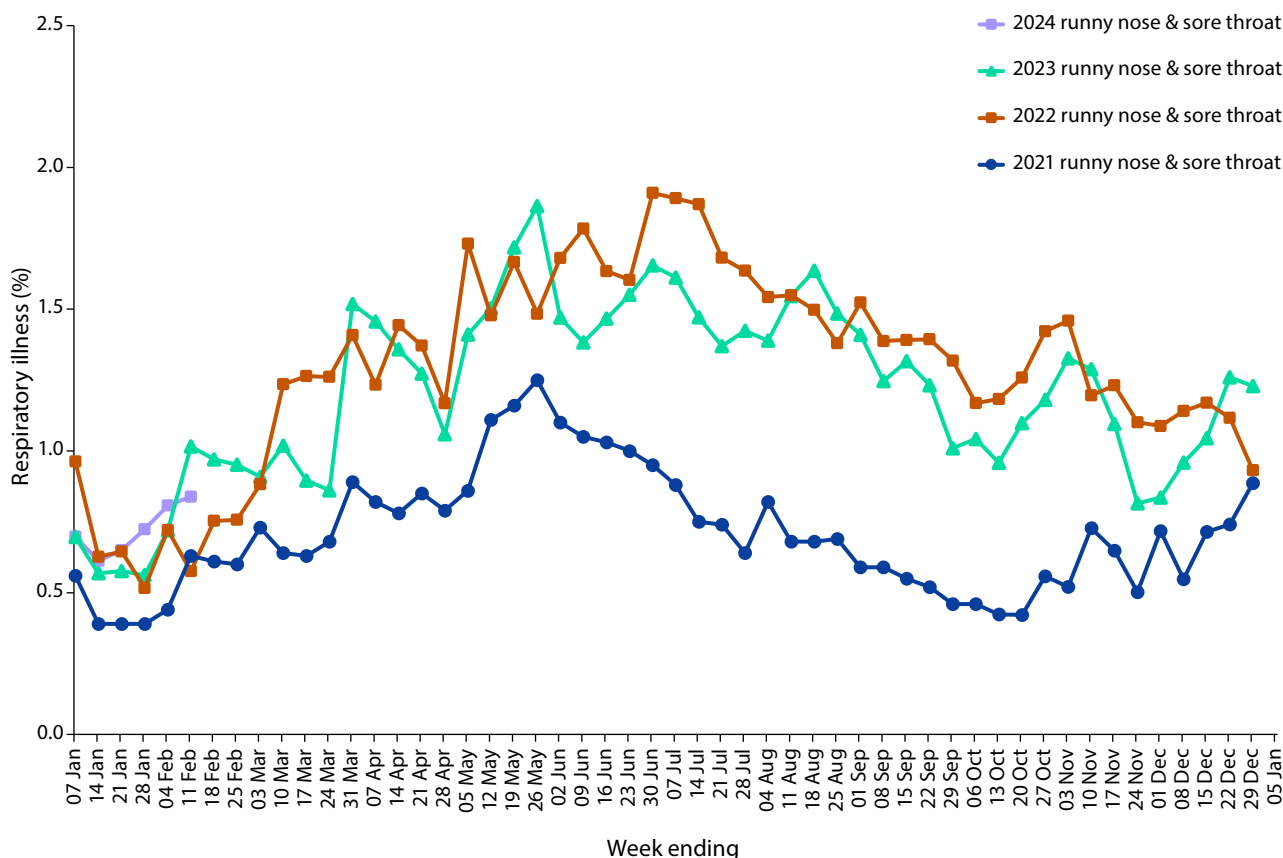

Week-on-week increases were observed in the incidence of 'runny nose and sore throat' symptoms between late November and December 2023, followed by a substantial decrease in recent weeks. In the current four-week reporting period, the average proportion of 'runny nose and sore throat' symptoms remains similar to the proportion observed during the same period in 2023, at 0.8% (Figure 10).

Over the reporting period, FluTracking data indicated that 11.1% of participants with 'fever and cough' were tested for SARS-CoV-2 with a PCR test and 79.5% were tested using a RAT (noting that in some instances RATs will be followed up by a PCR test for the same case). Of those with 'runny nose and sore throat', 3.0% were tested for SARS-CoV-2 using a PCR test and 54.1% were tested using a RAT. In the current reporting period, the percent positivity for 'fever and cough' symptoms increased for PCR (33.3%) and decreased for RAT (55.7%) compared

to the previous reporting period. For 'runny nose and sore throat' symptoms, the percent positivity remained largely unchanged for both PCR (12.5%) and RAT (14.7%). Note that participants with one set of symptoms are not excluded from having the other. It is important to acknowledge that there may be legitimate reasons why people did not get tested, including barriers to accessing testing. Symptoms reported to FluTracking are not specific to COVID-19 and may also be due to infections with other respiratory pathogens and to chronic diseases, such as asthma.

In the current reporting period, of those presenting to sentinel ASPREN sites with influenza-like illness who were tested for respiratory viruses, 52.5% (31/59) tested positive for a respiratory virus. Among those positive, the most common viruses detected were rhinovirus (35.5%; 11/31) followed by SARS-CoV-2 (29.0%; 9/31), and metapneumovirus (12.9%; 4/31).

Figure 10: Weekly trends in runny nose and sore throat symptoms amongst FluTracking survey participants (age-standardised), Australia, 1 January 2021 – 11 February 2024^a

a Data on runny nose and sore throat were only collected systematically after 29 March 2020, therefore a historical average for this symptom profile is unavailable.

COVID-19 trends by WHO region

As of 4 February 2024, over 774 million COVID-19 cases and over 7 million deaths have been reported globally since the start of the pandemic, with a global case fatality rate (CFR) of approximately 0.91%.¹² Current trends in reported COVID-19 cases are an underestimate of the true number of global infections due to the reduction in testing and reporting in many countries. For more information, please refer to the WHO monthly COVID-19 epidemiological update.¹³

Acknowledgements

We thank public health staff from incident emergency operations centres and public health units in state and territory health departments, and the Australian Government Department of Health and Aged Care, along with state and territory public health laboratories. We thank those who have provided data from surveillance systems, such as ASPREN, FluTracking, FluCAN, PAEDS, SPRINT-SARI, the Communicable Disease Genomics Network, AusTrakka and jurisdictional sequencing laboratories.
